

THE SCHOOL OF AI

NAVTTTC

What AI actually is

Week 1, Day 2 — Workplace ethics, the core concepts, the difference between AI, machine learning, deep learning and generative AI, and how we got here.

One day of theory, then we build

After today you will be able to use the words the industry uses, and know what they mean.

-
- | | | |
|---|---------------------------------|--|
| 1 | Hour 1 · Ethics | How you behave at work and with client data. The part that decides whether anyone hires you twice. |
| 2 | Hour 2 · What AI is | Plain definitions, the words you will hear daily, and what these tools cannot do. |
| 3 | Hour 3 · The four terms | AI, machine learning, deep learning and generative AI — and where your tools sit. |
| 4 | Hour 4 · How we got here | From rules written by hand to agents that take actions. Including the two times AI collapsed. |
-

Skill gets you the first job. Conduct gets you the second.

Every rule in this hour is something a client, an employer or an institute can see — and does check.

The ten work ethics

ETHIC	WHAT IT MEANS HERE, IN A DIGITAL AND REMOTE WORKPLACE
Attendance	Be present and punctual. Working remotely, this becomes replying and delivering on time.
Character	Honesty above all. Review AI output before you send it; never pass it off as expert analysis.
Team work	Carry your weight, help those behind, and know when to blend your idea into someone else's.
Appearance	Presentation counts — and online that means your profile, your photo and your messages.
Attitude	Accept correction, admit mistakes, keep learning as the tools change under you.
Productivity	Quality and timeliness. Know when AI should speed you up and when judgement is required.
Organisation	Manage your time and keep prompts, workflows and client files in order you can find.
Communication	Write clearly and say plainly what AI can and cannot do for a client. That is your job.
Cooperation	Follow institute rules, adapt to new tools and situations without complaint.
Respect	Respect people, different opinions, and above all the privacy of client and user data.

Four rules for AI work, starting today

These are not optional extras. In 2026 they are what separates a professional from someone who pastes and hopes.

Read before you send

Every AI output is a draft until a person has checked it. You are responsible for what you deliver, not the tool.

Protect client data

Do not paste customer records, ID numbers or private documents into a public AI tool without permission.

Check the facts

These tools state wrong things confidently. Names, dates, figures and laws must be verified elsewhere.

Be honest about AI

If a client asks whether AI was used, say yes and explain your process. Most of them already assume it.

Ordinary software follows rules. AI learns patterns from examples.

That one difference explains everything else today — why AI can write an email, why it sometimes invents facts, and why it needs so much data.

Two ways to make a computer decide

Take one task — sorting spam out of an inbox — and look at how each approach handles it.

The old way: written rules

A person writes the rules by hand: if the subject line says "free prize", mark it spam.

It works until a spammer writes "free prize". Then a human must add another rule, forever.

Predictable, easy to explain, and completely unable to handle anything nobody anticipated.

The AI way: learned patterns

You show the system a million emails already marked spam or not spam.

It works out for itself what spam tends to look like, including tricks nobody wrote down.

Powerful and adaptable — but it can be confidently wrong, and it cannot always explain why it decided.

How an AI tool gets made

Four steps. You will never do steps one to three — but you must understand them to use step four well.

1	Data	Enormous amounts of text, images or audio are gathered. Whatever is in the data shapes what the model can do — and which biases it carries.
2	Training	Powerful computers run over that data for weeks, adjusting billions of internal settings until the model predicts well.
3	The model	The finished file of learned settings. This is what people mean by GPT-6, Claude Fable 5.1 or Gemini 3.8 Flash.
4	Using it	You send a prompt, the model responds. This is inference, and it is the only step you will ever touch.

Seven words you will hear every day

WORD	WHAT IT MEANS, IN PLAIN LANGUAGE
Model	The trained AI itself. Claude, GPT and Gemini are families of models.
Prompt	What you type in. The instruction. Week 4 is entirely about writing these well.
Token	A chunk of text, roughly three-quarters of a word. Tools count and charge by these.
Context window	How much text a model can hold in mind at once. Bigger means longer documents.
Hallucination	When a model states something false with complete confidence. The main risk in your work.
Multimodal	A model that handles text, images, audio and video rather than text alone.
Agent	A model given tools and permission to take actions, not just answer questions.

Four things these tools cannot do

Knowing the limits is what makes you useful. Anyone can paste a prompt; you are being trained to catch what comes back wrong.

Guarantee truth

A model produces likely-sounding text, not verified fact. Confidence is not evidence.

Know today's news

Each model has a training cut-off. Without web search, recent events are invisible to it.

Know your context

Your client, your city, your market, your regulations. You supply that; the model cannot.

Take responsibility

If the output is wrong and it goes out under your name, it is your mistake, not the tool's.

One sits inside the other

People use these four words as if they mean the same thing. They do not — each is a smaller box inside the one before.

Artificial intelligence

The whole field. Any machine doing something that normally needs human thinking.

Machine learning

The part of AI where systems learn from examples instead of hand-written rules.

Deep learning

Machine learning using very large layered networks. What made the last decade possible.

Generative AI

Deep learning that produces new text, images, audio or video. Your daily tools.

The same four, with examples

TERM	IN ONE SENTENCE	SOMETHING YOU HAVE ALREADY USED
Artificial intelligence	Machines doing tasks that need human-like thinking	A chess program; a bank's fraud alert
Machine learning	Systems that learn the pattern from examples	Your email spam filter; YouTube recommendations
Deep learning	Learning with large layered neural networks	Face unlock on your phone; voice typing in Urdu
Generative AI	Models that create new content on request	ChatGPT, Claude, Gemini, AI image and video tools

All four are AI. Only the last one writes your email.

A chatbot predicts what word should come next. That is all.

Do it well enough, billions of times over, and it looks like understanding. Remembering that it is prediction — not knowledge — is exactly why you check its facts.

Seventy years of writing rules

WHEN	WHAT HAPPENED	WHY IT MATTERED
1950	Alan Turing asks whether machines can think	The question that started the field
1956	A workshop at Dartmouth names it "artificial intelligence"	The field gets its name and its first funding
1960s–70s	Rule-based programs and ELIZA, the first chatbot	Impressive, but every rule was written by a human
1980s	Expert systems sold to business	The first commercial wave — and the first collapse
1997	Deep Blue beats the world chess champion	Raw calculation, not learning. Narrow and brittle

AI has collapsed twice before

Both times the pattern was the same: big promises, disappointing delivery, funding withdrawn. They are called the AI winters.

First winter · mid-1970s

Researchers had promised human-level translation and reasoning within a decade. The computers of the day could not deliver, and governments cut the money.

Second winter · late 1980s

Expert systems were sold to thousands of companies, then proved expensive to maintain and impossible to scale. The market for them disappeared.

The lesson for you: build skills that survive the hype, not skills tied to one product.

Then machines started learning

WHEN	WHAT HAPPENED	WHY IT MATTERED
2012	Deep learning wins a large image-recognition contest	Machines learn features from data instead of rules
2017	Google researchers publish the Transformer design	The architecture underneath every chatbot you use
2022	ChatGPT opens to the public	AI stops being research and becomes a consumer product
2023–25	Multimodal models; text, image, audio and video together	One tool can now read a photo and write about it
2026	Agents: models given tools and permission to act	AI moves from answering to doing work end to end

Where the technology stands today

The shift of this year is agents — AI that is given tools and permission to take actions inside real systems.

57%

of surveyed organisations already run multi-step agent workflows

86%

have moved coding agents past experiments and into production work

46%

say their hardest problem is connecting AI to existing systems — not intelligence

Note what the third number says.

The bottleneck is plumbing, not brainpower. Connecting tools together is the skill this course spends five weeks teaching.

Source: 2026 State of AI Agents Report, Anthropic, surveying over 500 technical leaders. Enterprise sample — treat as direction of travel, not a local figure.

Task 2 · Learn ethics

From Annexure-I. Two parts, both handwritten or typed into your task file.

1

Your top ten values

List the professional values you want to be known for, then put them in order. Ten, ranked, in your own words — not copied from the slide.

2

One paragraph

Write a short paragraph on responsible AI use in the profession you chose yesterday. What will you always check before sending work to a client?

Also: keep using the three accounts you opened. Ask each of them one question every day.

END OF DAY 2

**You now know what these tools are.
Tomorrow, what kinds there are.**

Next · Day 3 — Narrow, general, generative and conversational AI, and where AI is already sitting in your daily life: search, recommendations, navigation and voice assistants.
